## Lecture 18: Central Limit Theorem 2

---

Hwiyoung Lee

October 14, 2019

Department of Statistics, Florida State University

# Review of CLT

- The central limit theorem states that if you have a population with mean  $\mu$  and standard deviation  $\sigma$  and take **sufficiently large random samples** ( $n \geq 30$ ) from the population, then the distribution of the sample means will be **approximately normally distributed**.
- This will hold true **regardless of** the shape of population distributions (Bell, skew, bimodal, uniform)

# Review of CLT

# CLT Simulation (Bimodal)

Population Distribution

$$\mu = 55.2, \sigma = 19.5$$

Sampling Distribution of the Sample Mean

Mean = 55.1, Std Dev = 3.45 (10,000 simulations of samples of size  $n = 30$ )

# CLT Simulation (Skewed)

Population Distribution

$$\mu = 10, \sigma = 7.75$$

Sampling Distribution of the Sample Mean

Mean = 9.99, Std Dev = 1.4 (10,000 simulations of samples of size  $n = 30$ )

# CLT Simulation (Uniform)

Population Distribution

$\mu = 50, \sigma = 28.9$

Sampling Distribution of the Sample Mean

Mean = 49.9, Std Dev = 5.2 (10,000 simulations of samples of size  $n = 30$ )

## Example : CLT

- Original population of data : 2, 4, 6, 8
- Population mean  $\mu = (2 + 4 + 6 + 8)/4 = 5$
- Draw random samples (size  $n=2$ )

| Samples | $\bar{X}$ | Samples | $\bar{X}$ | Samples | $\bar{X}$ | Samples | $\bar{X}$ |
|---------|-----------|---------|-----------|---------|-----------|---------|-----------|
| 2,2     |           | 4,2     |           | 6,2     |           | 8,2     |           |
| 2,4     |           | 4,4     |           | 6,4     |           | 8,4     |           |
| 2,6     |           | 4,6     |           | 6,6     |           | 8,6     |           |
| 2,8     |           | 4,8     |           | 6,8     |           | 8,8     |           |

Average of the sample means : \_\_\_\_\_

## Example : CLT

Distribution of  $\bar{X}$

|   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|
|   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |
| 2 | 3 | 4 | 5 | 6 | 7 | 8 |

Sampling distributio of  $\bar{X}$  roughly follows normal distribution

## Example : CLT

1. How many keys do you have on you right now? \_\_\_\_\_
2. Fill in the table below

| Group Member Name | Number of keys |
|-------------------|----------------|
|                   | A =            |
|                   | B =            |
|                   | C =            |
|                   | D =            |

3. Calculate the following averages

|           |  |           |  |           |  |
|-----------|--|-----------|--|-----------|--|
| $(A+B)/2$ |  | $(A+C)/2$ |  | $(A+D)/2$ |  |
| $(B+C)/2$ |  | $(B+D)/2$ |  | $(C+D)/2$ |  |

# Central Limit Theorem

- $\bar{X}$  is an estimator of the population mean  $\mu$  because we can, and we often do, use our particular sample result  $\bar{X}$  as an estimate of  $\mu$ .
- $\bar{X}$  is an **unbiased estimator** of the population mean, because the mean of the  $\bar{X}$ 's is equal to the population mean.

# Central Limit Theorem

- In general, sample means vary less than individual values.
  - Individual value :  $X \sim N(\mu, \sigma)$
  - Sample means :  $\bar{X} \sim N\left(\mu, \frac{\sigma}{\sqrt{n}}\right)$
- In general, larger samples produce values of  $\bar{X}$  that stay closer to  $\mu$ . It follows that a **larger sample is more likely to give us a better estimate of  $\mu$  than a smaller sample.**

# Central Limit Theorem

# Central Limit Theorem

## Exercise

# Male weight

## Male weight

Assume that weights of men are normally distributed with a mean of 170 lb and a standard deviation of 30 lb.

- What percentage of **individual** men have weights less than 185 lb?
- If samples of 36 men are randomly selected and the mean weight is computed for each sample, what percentage of **the sample means** are less than 185 lb?

## Male weight

- What percentage of **individual** men have weights greater than 167 lb?
- If samples of 100 men are randomly selected and the mean weight is computed for each sample, what percentage of **the sample means** are greater than 167 lb?

## Test Scores

You are a middle school principal and your 100 eighth-graders are about to take a national standardized test. The test is designed so that the mean score is  $\mu = 400$  with a standard deviation of  $\sigma = 70$ . Assume the scores are normally distributed.

- What is the likelihood that one of your eighth-graders, selected at random, will score below 375 on the exam?

- Your performance as a principal depends on how well your entire group of eighth-graders scores on the exam. What is the likelihood that your group of 100 eighth-graders will have a mean score below 375?

Two sampling distributions of  $\bar{X}$  are described below. Which sampling distribution will have the lower standard deviation?

1. SRSs of 4 subjects each are selected and the mean is calculated for each sample.
2. SRSs of 16 subjects each are selected and the mean is calculated for each sample.

## Sample Size

Match the sampling distributions of  $\bar{X}$  shown below to these sample sizes:  $n=1$ ,  $n=2$ ,  $n=3$ .

When  $n=1$ , the sampling distribution of  $\bar{X}$  is the same as the distribution of the individual values  $X$ , so it is the same as the original population distribution.

Section 15 : MWF (10:10 ~ 11:00)

- Test Date : Oct 21 (Mon) HCB 217

Section 05 : MWF (12:20 ~ 1:10)

- Test Date : Oct 18 (Fri) OSB 108
